Data structure that can handle point/range update and point/range queries for invertible operations. Obs: If the operation is not easily invertible (e.g. min,max,gcd), it can only answer prefix queries

```

1 // [l,r] interval convention and 0-indexed parameters
2 struct BIT {
3     vector<ll> bit;
4     int n;
5     BIT(int _n = 0){
6         n = _n;
7         bit.assign(n+1,0ll);
8     }
9     ll presum(int i){
10         ll ans = 0;
11         for (++i; i > 0; i -= i&-i)
12             ans += bit[i];
13         return ans;
14     }
15     ll sum(int l, int r){
16         return presum(r) - presum(l-1);
17     }
18     void add(int i, ll v){
19         for (++i; i <= n; i += i&-i)
20             bit[i] += v;
21     }
22 };

```

2.2 BIT (Fenwick Tree) 2D

2D Sum BIT, update and sum. The struct encapsulates the 1-based indexing, therefore parameters are 0-based indexed.

Query/update time: $\mathcal{O}(\log n \cdot \log m)$

Construction time (using proper constructor): $\mathcal{O}(nm)$

Space: $\mathcal{O}(nm)$

```

1 // [l,r] interval cnvention and 0-based indexing
2 struct BIT2D {
3     vector<vector<ll>> bit;
4     int n, m;
5     BIT2D(int _n, int _m){
6         n = _n; m = _m;
7         bit.assign(n+1,vector<ll>(m+1));
8     }
9     BIT2D(vector<vector<ll>> &a) {
10         n = a.size();
11         m = a[0].size();
12         bit.assign(n+1, vector<ll>(m+1));
13     }
14     for (int i = 1; i <= n; i++)
15         for (int j = 1; j <= m; j++)
16             bit[i][j] = a[i-1][j-1];

```

```

17
18     for (int i = 1; i <= n; i++) {
19         for (int j = 1; j <= m; j++) {
20             int nxt = j + (j&-j);
21             if (nxt <= m) bit[i][nxt] += bit[i][j];
22         }
23     }
24     for (int i = 1; i <= n; i++) {
25         int nxt = i + (i&-i);
26         if (nxt <= n) {
27             for (int j = 1; j <= m; j++)
28                 bit[nxt][j] += bit[i][j];
29         }
30     }
31 }
32 void add(int si, int sj, ll v){
33     for(int i = si+1; i <= n; i+=i&-i)
34         for (int j = sj+1; j <= m; j+=j&-j)
35             bit[i][j] += v;
36 }
37 ll presum(int si, int sj){
38     ll ans = 0;
39     for (int i = si+1; i > 0; i-=i&-i)
40         for (int j = sj+1; j > 0; j-=j&-j)
41             ans += bit[i][j];
42     return ans;
43 }
44 ll sum(ii ab, ii cd){
45     auto [a,b] = ab;
46     auto [c,d] = cd;
47     return presum(c,d) - presum(a-1,d) - presum(c,b-1)
48         + presum(a-1,b-1);
49 }

```

2.3 DSU - Disjoint Set Union

Query/update time: $\mathcal{O}(1)$

Construction time: $\mathcal{O}(n)$

Space: $\mathcal{O}(n)$

```

1 struct DSU {
2     vi p, sz;
3     DSU(int n) {
4         p.resize(n);
5         iota(p.begin(), p.end(), 0);
6         sz.assign(n, 1);
7     }
8     int find(int i) {
9         if (p[i] == i) return i;
10        return p[i] = find(p[i]);
11    }
12    bool join(int u, int v) {
13        u = find(u);
14        v = find(v);
15        if (u == v) return false;
16        if (sz[u] < sz[v]) swap(u, v);
17        p[v] = u;
18        sz[u] += sz[v];
19        return true;
20    }
21 };

```

2.4 DSU - Binary Tree

Specific code to find maximum path sums between pairs of vertices. Uses Kruskal-style MST. Query/update time: possibly $\mathcal{O}(n)$ Construction time: $\mathcal{O}(n)$ Space: $\mathcal{O}(n)$

```

1 vi d;
2 vi_ii e;
3 vi ans;
4
5 int merged;
6 vi _p, _leaf, _wei;
7 vvi adj;
8 int _find(int u) { return _p[u] == u ? u : _p[u] = _find(_p[u]); }
9 void _union(int u, int v, int w){
10     u = _find(u);
11     v = _find(v);
12     int merge_ind = merged+n;
13     _p[u] = merge_ind;
14     _p[v] = merge_ind;
15     _leaf[merge_ind] = _leaf[u] + _leaf[v];
16     _wei[merge_ind] = max(_wei[u], _wei[v]);
17     adj[u].push_back(merge_ind);
18     adj[merge_ind].push_back(u);
19     adj[v].push_back(merge_ind);
20     adj[merge_ind].push_back(v);
21     merged++;
22 }
23 void make(){
24     _p = vi(2*n);
25     for(int i = 0; i < 2*n; i++) _p[i] = i;
26     _leaf = vi(2*n, 1);
27     _wei = vi(2*n);
28     for(int i = 0; i < n; i++) _wei[i] = d[i];
29     merged = 0;
30     adj = vvi(2*n);
31 }
32
33 void dfs(int u, int p){
34     for(auto &v: adj[u]){
35         if(v == p) continue;
36         ans[v] = ans[u] + (_leaf[u] - _leaf[v])*_wei[u];
37         dfs(v, u);
38     }
39 }

```

2.5 MinQueue

Minimum (or maximum) queue. All operations are $\mathcal{O}(1)$ on average. Useful for fixed length max/min queries

```

1 template<typename T>
2 struct MinQueue{
3     deque<pair<T,int>> q;
4     int added = 0;
5     int removed = 0;
6     // returns [value, index]
7     pair<T,int> getmin(){ return q.front(); }
8
9     void push(T x){
10        // < for MaxQueue
11        while (!q.empty() && q.back().first > x) q.
12            pop_back();
13        q.push_back({x, added++});
14    }

```

```

14 void pop(){
15     if (!q.empty() && q.front().second == removed) q.
16         pop_front();
17     removed++;
18 }
19 bool empty() { return added == removed; }

```

2.6 Mo's Algorithm

A technique for solving offline range queries on static arrays by sorting queries to minimize total pointer movement. It processes intervals by incrementally updating the range via `add` and `remove` operations. With the optimal block size, the time complexity is $\mathcal{O}((N+Q)\sqrt{N})$ or $\mathcal{O}(N\sqrt{Q})$, depending on block size choice ($\sqrt{N}$ or $N/\sqrt{Q}$). This example solves queries for distinct elements in range

```

1 struct Mo {
2     struct Query {
3         int l, r, idx, b;
4         bool operator<(const Query& o) const {
5             return b != o.b ? b < o.b :
6                 (b & 1 ? r > o.r : r < o.r);
7         }
8     };
9
10    int n, block_sz;
11
12    // custom stuff
13    vi freq, a;
14    int ans = 0;
15
16    vector<Query> queries;
17    Mo(int n) : n(n), block_sz(round(sqrt(n))) {}
18
19    // [l,r] indexed
20    void add_query(int l, int r, int i) {
21        queries.push_back({l,r,i,l/block_sz});
22    }
23    void add(int i) {
24        // add val at i
25        freq[a[i]]++;
26        if (freq[a[i]] == 1) ans++;
27    }
28    void remove(int i) {
29        // remove value at i
30        freq[a[i]]--;
31        if (freq[a[i]] == 0) ans--;
32    }
33    int get_ans() {
34        // compute current answer
35        return ans;
36    }
37
38    vi run() {
39        vi ans(queries.size());
40        sort(queries.begin(), queries.end());
41        int l = 0, r = -1;
42        for (auto& q : queries) {
43            while (l > q.l) add(--l);
44            while (r < q.r) add(++r);
45            while (l < q.l) remove(l++);
46            while (r > q.r) remove(r--);
47            ans[q.idx] = get_ans();

```

```

48     }
49     return ans;
50 }
51 };

```

2.7 Mo with updates

Also sorts queries to minimize total pointer movement, but now there is an added dimension for time (POINT updates). $\mathcal{O}(QN^{2/3})$

```

1 struct MoUpdate {
2     int n;
3     const int block_sz;
4     struct Query {
5         int l,r,t,id;
6     };
7     vector<Query> queries;
8     vector<ii> updates;
9     vector<int> a;
10
11     MoUpdate(vector<int> &v, int q) : block_sz(round(cbrt(
12         (2*v.size()*v.size())))) {
13         n = v.size() + q;
14         a = v;
15         init();
16     }
17     void add_query(int l, int r) {
18         queries.push_back({l,r,(int)updates.size(),(int)
19             queries.size()});
20     }
21     void add_update(int i, int x) {
22         updates.push_back({i,x});
23     }
24     void update(int l, int r, int t) {
25         auto &[i,v] = updates[t];
26         if (l <= i && i <= r) remove(i);
27         swap(a[i],v);
28         if (l <= i && i <= r) add(i);
29     }
30     vector<int> run() {
31         vector<int> ans(queries.size());
32         sort(queries.begin(),queries.end(), [&](Query qa,
33             Query qb){
34             int l = qa.l/block_sz;
35             int r = qa.r/block_sz;
36             int ql = qb.l/block_sz;
37             int qr = qb.r/block_sz;
38             using iii = tuple<int,int,int>;
39             return iii(l, l&1 ? -r:r, r&1 ? qa.t:-qa.t) <
40                 iii(ql, ql&1 ? -qr:qr, qr&1 ? qb.t:-qb.t);
41         });
42         int l = 0, r = -1, t = 0;
43         for (auto &q : queries) {
44             while(t < q.t) update(l,r,t++);
45             while(t > q.t) update(l,r,t--);
46             while(l > q.l) add(--l);
47             while(r < q.r) add(++r);
48             while(l < q.l) remove(l--);
49             while(r > q.r) remove(r--);
50             ans[q.id] = get_ans();
51         }
52         return ans;
53     }
54
55     // customize depending on problem
56     int ans = 0;

```

```

54 void init(){
55     // initialize custom stuff
56 }
57 void remove(int i) {
58     // remove a[i] from the current ans
59 }
60 void add(int i) {
61     // add a[i] to the current ans
62 }
63 int get_ans() {}
64 };

```

2.8 Segment Tree

2.8.1 Iterative Point Update

Best for: Standard point updates and range queries (e.g., Point Add + Range Sum).

- **Performance:** Best possible.
- **Memory:** Best possible; $2n$ allocation.
- **Use Case:** If no range updates, then use this.

2.8.2 Iterative Lazy

Best for: Index-independent range updates (e.g., Range Add, Range Set, Range Max, Range Flip).

- **Performance:** Noticeably faster than recursive lazy trees.
- **Index Blindness:** If the update depends on the range indexes themselves (such as AP addition), use the recursive lazy one.

2.8.3 Recursive Lazy

Best for: Index-dependent updates (e.g. AP addition), Tree Walking (Binary Search on Tree), and persistency.

- **Performance:** It is the slowest of the three, use only if necessary.

2.8.4 Usage

You should (almost) never alter the `segtree` logic. Ideally you only modify the `node` struct by answering four questions:

1. `tag`: What data does a range update carry? (e.g., a single integer for addition, or a pair of integers a, d for an AP).

2. `apply()`: How does a `tag` mathematically alter the state of a single node?
3. `push()`: How does a parent node transfer its pending `tag` to its left and right children?
4. `combine()`: How do you calculate the state of a parent by merging the states of its children?

```

1 // ITERATIVE - implemented for sum + point assignment
2 struct segtree {
3     struct node {
4         int sum = 0; // data
5         static node combine(const node& a, const node& b) {
6             return {a.sum + b.sum};
7         }
8         void apply(int v) {
9             sum = v;
10        }
11    };
12    int n;
13    vector<node> t;
14    void init(const vi& a) {
15        n = a.size();
16        t.assign(2*n, node());
17        for (int i = 0; i < n; i++) t[n + i].apply(a[i]);
18        for (int i = n-1; i > 0; i--) t[i] = node::combine(
19            t[i<<1], t[i<<1|1]);
20    }
21    void set(int p, int v) {
22        for (t[p] += n].apply(v), p >= 1; p > 0; p >= 1) {
23            t[p] = node::combine(t[p<<1], t[p<<1|1]);
24        }
25    }
26    node query(int l, int r) {
27        node resL, resR;
28        for (l+=n, r+=n; l < r; l>=1, r>=1) {
29            if (l&1) resL = node::combine(resL, t[l++]);
30            if (r&1) resR = node::combine(t[--r], resR);
31        }
32        return node::combine(resL, resR);
33    }
34
35    // LAZY ITERATIVE - implemented for sum + range
36    // TODO: test
37    struct segtree {
38        struct node {
39            struct tag {
40                int add = 0;
41                bool has = false;
42            };
43            int sum = 0; // data
44            int len = 0;
45            tag lazy;
46        };
47        static node combine(const node& a, const node& b) {
48            if (a.len == 0) return b;
49            if (b.len == 0) return a;
50            return {a.sum + b.sum, a.len + b.len, {0, false}};
51        }
52        void apply(tag t) {

25    }
26    inline ii f(ii l, ii r) { return std::min(l,r); }
27 };

```

3 Graphs

3.1 BFS 0-1

Time: $\mathcal{O}(n + m)$

```

1 vi bfs01(int s){
2     vi d(n, INF);
3     d[s] = 0;
4     deque<int> q;
5     q.push_front(s);
6     while(!q.empty()){
7         int u = q.front(); q.pop_front();
8         for (auto [w,v] : adj[u]){
9             if (d[u]+w < d[v]){

```

```

10     d[v] = d[u] + w;
11     if (w == 1) q.push_back(v);
12     else q.push_front(v);
13 }
14 }
15 }
16 return d;
17 }

```

3.2 Block Cut Tree (BCT)

A data structure that condenses an undirected graph into a bipartite graph using two types of nodes: B-nodes (biconnected components) and C-nodes (articulation points). Edges strictly connect a B-node to a C-node if the articulation point belongs to that component. Yields exactly one tree per connected component.

Articulation points are explicitly represented as the C-nodes. Because an articulation point is a vertex that disconnects a component upon removal, it acts as a literal bridge in the BCT. Any path navigating between two distinct biconnected components in the original graph is forced to route through the shared C-node.

```

1 vvi build_bct(const vvi &adj){
2     int n = adj.size();
3     vi in(n,-1), low(n), st;
4     int timer = 0;

4 DP

4.1 Bin Packing

Time: $\mathcal{O}(n \cdot 2^n)$ Space: $\mathcal{O}(2^n)$

```

1 vi w(n);
2
3 vector<ii> dp(1<<n, ii(INF,0));
4 // dp[i] = for the subset i(bitmask) (A,B) is the pair
5     where
6     // A - the min number of knapsacks to store this subset
7     // B - the min size of a used knapsack
8
9 dp[0] = ii(0, INF);
10 for (int subset = 1; subset < (1<<n); subset++){
11     for (int item = 0; item < n; item++){
12         if (!((subset>>item)&1)) continue;
13         int prevsubset = subset - (1<<item);
14         ii prev = dp[prevsubset];
15
16         if (prev.second + w[item] <= x) {
17             // can fill the knapsack, fill it
18             dp[subset] = min(dp[subset], ii(prev.first, prev.
19                 second+w[item]));
20         } else {
21             // cant fill the knapsack, create a new one
22             dp[subset] = min(dp[subset], ii(prev.first+1, w[
23                 item]));
24         }
25     }
26 }
27
28 cout << dp[(1<<n)-1].first << endl;

```

4.2 Broken Profile DP

Solves the problem of counting how many ways to fill an $n \times m$ grid using 1×2 tiles. This technique can be used whenever the state dependence is only on the previous state (column). Time: $\mathcal{O}(mn2^n)$ Space: $\mathcal{O}(mn2^n)$

```

1 int dp[1002][12][1024];
2 dp[0][0][0] = 1;
3
4 for (int i = 0; i < m; i++){
5     for (int j = 0; j < n; j++){
6         for (int mask = 0; mask < (1<<n); mask++){
7             if (mask & (1<<j)){
8                 int nxt_mask = mask - (1<<j);
9                 dp[i][j+1][nxt_mask] += dp[i][j][mask];
10                dp[i][j+1][nxt_mask] %= M;
11            } else {
12                int q = mask + (1 << j);
13                dp[i][j+1][q] += dp[i][j][mask];
14                dp[i][j+1][q] %= M;
15                if (j < n-1 && (mask & (1<<(j+1)))==0){
16                    q = mask + (1 << (j+1));
17                    dp[i][j+1][q] += dp[i][j][mask];
18                    dp[i][j+1][q] %= M;
19                }
20            }
21        }
22    }
23
24    for (int p = 0; p < (1<<n); p++){
25        dp[i+1][0][p] = dp[i][n][p];
26    }
27 }

```

4.3 Convex Hull Trick (CHT)

• Recurrence form:

TODO formulas

- **Slope monotonicity:** If coefficients a_j (slopes) are inserted in strictly decreasing (or increasing) order as j grows, and
- **Query monotonicity:** Values x_i for query come in non-decreasing (min) or increasing (max) order consistent with slope order,

• Complexity:

- Insertion + amortized query in $\mathcal{O}(1)$ per operation (pointer walk) under monotonicity.
- Non-monotonic case, generic CHT via binary search: $\mathcal{O}(\log n)$ per query.
- General alternative: Li Chao Tree for insertion/s/queries in arbitrary order, $\mathcal{O}(\log M)$ per operation (where M is the domain of x).

• Constraints:

- If it cannot be written in linear form, CHT does not apply.
- If there is no monotonicity of slopes or queries, consider Li Chao Tree or CHT variant with binary search.

The example below solves the dp where the recurrence is:

TODO formulas

```

1 struct CHT {
2     struct Line { // y = mx + c
3         int m, c;
4         Line(int m, int c) : m(m), c(c) {}
5         int val(int x){
6             return m*x + c;
7         }
8         int floorDiv(int num, int den) {
9             if (den < 0) num = -num, den = -den;
10            if (num >= 0) return num / den;
11            else return - ( (-num + den - 1) / den );
12        }
13        int ceilDiv(int num, int den) {
14            if (den < 0) num = -num, den = -den;
15            if (num >= 0) return (num + den - 1) / den;
16            else return - ( (-num) / den );
17        }
18        int intersect(Line l){
19            // m1x + c1 = m2x + c2
20            // x = (c2 - c1)/(m1 - m2)
21            // if slopes are increasing, use floor div
22            return ceilDiv(l.c - c, m - l.m);
23        }
24    };
25
26    deque<pair<Line, int>> dq;
27
28    void insert(int m, int c){

74     int n, c; cin >> n >> c;
75     vi h(n);
76     for (auto &x : h) cin >> x;
77
78     vi dp(n);
79     dp[0] = 0;
80     CHT cht;
81     cht.insert(-2*h[0], h[0]*h[0]);
82     for (int i = 1; i < n; i++){
83         dp[i] = cht.query(h[i]) + c + h[i]*h[i];
84         cht.insert(-2*h[i], h[i]*h[i] + dp[i]);
85     }
86     cout << dp[n-1] << endl;
87 }

```

4.4 Edit Distance (Levenshtein)

Very similar to LCS, in the sense that it considers prefixes already computed. Time: $\mathcal{O}(mn)$ Space: $\mathcal{O}(mn)$

```

1 vvi dp(n+1, vi(m+1));
2 for (int i = 0; i <= n; i++) dp[i][0] = i;
3 for (int i = 0; i <= m; i++) dp[0][i] = i;
4 for (int i = 1; i <= n; i++){
5     for (int j = 1; j <= m; j++){
6         dp[i][j] = min(
7             min(dp[i][j-1]+1, dp[i-1][j]+1),
8             dp[i-1][j-1]+(s[i-1]!=t[j-1])
9         );
10    }
11 }

```

4.5 Knapsack - 1D

The spirit here is the same as the 2D version, but here it iterates on the knapsack capacity backwards, to ensure that the value of $dp[j-w[i]]$ is not considering the item i . Time: $\mathcal{O}(nW)$ Space: $\mathcal{O}(W)$

```

1 vi dp(W+1);
2 for (int i = 0; i < n; i++){
3     for (int j = W; j >= w[i]; j--){
4         dp[j] = max(dp[j], v[i] + dp[j-w[i]]);
5     }
6 }

```

4.6 Knapsack - 2D

Time: $\mathcal{O}(nW)$ Space: $\mathcal{O}(nW)$

```
1 vvi dp(n+1, vi(W+1));
2 for (int c = 1; c <= W; c++){
3     for (int i = 1; i <= n; i++){
4         dp[i][c] = dp[i-1][w];
5         if (c-w[i-1] >= 0) {
6             dp[i][c] = max(dp[i][c], dp[i-1][c-w[i-1]] + v[i-1]);
7         }
8     }
9 }
```

4.7 LCS - Longest Common Subsequence

Subsequence generation included here. Time: $\mathcal{O}(mn)$
Space: $\mathcal{O}(mn)$

```
1 vvi dp(n+1, vi(m+1));
2 vvii p(n+1, vii(m+1));
3
4 for (int i = 1; i <= n; i++){
5     for (int j = 1; j <= m; j++){
6         if (a[i-1] == b[j-1]) {
7             dp[i][j] = dp[i-1][j-1]+1;
8             p[i][j] = {i-1, j-1};
9         } else if (dp[i][j-1] > dp[i-1][j]) {
10            dp[i][j] = dp[i][j-1];
11            p[i][j] = {i, j-1};
12        } else {
13            dp[i][j] = dp[i-1][j];
14            p[i][j] = {i-1, j};
15        }
16    }
17 }
18
19 ii pos = ii(n, m);
20 stack<int> st;
21 while (pos != ii(0, 0)) {
22     auto [i, j] = pos;
23     if (p[i][j] == ii(i-1, j-1)) st.push(a[i-1]);
24     pos = p[i][j];
25 }
26 cout << st.size() << endl;
27 while (!st.empty()) {
28     cout << st.top() << ' ';
29     st.pop();
30 }
31 cout << endl;
```

4.8 LiChao Tree

Generalization of CHT for linear functions that do not need to be sorted. Essentially a sparse segtree. Queries and insertions are all $\mathcal{O}(\log M)$. Where M is the size of the query interval the tree receives.

```
1 // Li Chao tree for minimum (or maximum) over domain [L, R].
2 // T should support +, *, comparisons.
```

```
3 // For integer x use eps = 0 and discrete mid+1 splitting;
4 // For floating use eps > 0 and continuous splitting without +1.
5 template<typename T>
6 struct lichao_tree {
7     // if max lichao, change to ::min()
8     static const T identity = numeric_limits<T>::max();
9
10    struct Line {
11        T m, c;
12        Line() { m = 0; c = identity; }
13        Line(T m, T c) : m(m), c(c) {}
14        T val(T x) { return m * x + c; }
15    };
16
17    struct Node {
18        Line line;
19        Node *lc, *rc;
20        Node() : lc(0), rc(0) {}
21    };
22
23    T L, R, eps;
24    deque<Node> buffer;
25    Node* root;
26
27    Node* new_node() {
28        buffer.emplace_back();
29        return &buffer.back();
30    }
31
32    lichao_tree() {}
33

78     if (r - l <= eps) return res;
79
80     // if max lichao, change min to max
81     if (x <= mid) return min(res, query(cur->lc, l, mid, x));
82     else return min(res, query(cur->rc, mid + 1, r, x));
83 }
84
85 void insert(T m, T c) { insert(root, L, R, Line(m, c)); }
86
87 T query(T x) { return query(root, L, R, x); }
88 }
```

4.9 LIS - Longest Increasing Subsequence

Time: $\mathcal{O}(n \log n)$

```
1 int lis(vi &a){
2     int n = a.size();
3     vi len(n+1, INF);
4     len[0] = -INF;
5     for (int i = 0; i < n; i++){
6         int l = upper_bound(all(len), a[i]) - len.begin();
7         if (len[l-1] < a[i] && a[i] < len[l]) len[l] = a[i];
8     }
9
10    int ans = 0;
11    for (int i = 0; i <= n; i++){
12        if (len[i] < INF) ans = i;
13    }
14    return ans;
15 }
```

4.10 SOSDP

```
1 int k; // amount of bits
2 vi a(1<<k);
3 // sosdp
4 for (int bit = 0; bit < k; bit++){
5     for (int mask = 0; mask < (1<<k); mask++){
6         if ((1<<bit) & mask) {
7             a[mask] += a[mask ^ (1<<bit)];
8         }
9     }
10 }
11
12 // do stuff (such as multiplication for OR convolution)
13
14 // sosdp inverse
15 for (int bit = 0; bit < k; bit++){
16     for (int mask = 0; mask < (1<<k); mask++){
17         if ((1<<bit) & mask) {
18             a[mask] -= a[mask ^ (1<<bit)];
19         }
20     }
21 }
```

4.11 Subset Sum

Almost identical to Knapsack, this code contains the subset reconstruction. Time: $\mathcal{O}(nS)$ Space: $\mathcal{O}(nS)$

```
1 vvi dp(n+1,vi(sum+1));
2 vvii p(n+1,vii(sum+1));
3
4 dp[0][0] = 1;
5
6 for (int i = 1; i <= n; i++){
7     for (int s = 1; s <= sum; s++){
8         if (s-a[i-1] >= 0 && dp[i-1][s-a[i-1]]){
9             // sum is possible taking item i
10            p[i][s] = {i-1,s-a[i-1]};
11            dp[i][s] = 1;
12        } else if (dp[i-1][s]) {
13            // sum not possible taking item i
14            // but still possible with other items (<i)
15            p[i][s] = {i-1,s};
16            dp[i][s] = 1;
17        }
18    }
19 }
20
21 if (!dp[n][target]) {
22     cout << -1 << endl;
23     return;
24 }
25
26 vi subset;
27 ii pos = {n,target};
28 while(pos != ii(0,0)){
29     auto [i,s] = pos;
30     if (p[i][s].second != s) subset.push_back(a[i-1]);
31     pos = p[i][s];
32 }
```

```
1 # Subset Sum with Bitset
2 If you only need reachability:
3 Time:  $\mathcal{O}(nS/w)$  (where  $w$  is sys word size)
4 Space:  $\mathcal{O}(S)$ 
```

5 Trees

5.1 Centroid Decomposition

Recursively splits a tree by its center of mass, building a "Centroid Tree" with a strictly guaranteed $\mathcal{O}(\log N)$ depth. Used for path queries where the tree is unrooted.

Build: $\mathcal{O}(N \log N)$

Sample is solving "count distinct paths with number of edges between k_1 and k_2 "

```
1 struct CentroidDecomposition{
2     vvi t, ct;
3     vi sz, added, cp;
4     int n, root;
5     CentroidDecomposition(const vvi &adj, int _k1, int
6         _k2)
```

```
7     t = adj,
8     n = adj.size();
9     cp = sz = added = vi(n);
10    root = -1;
11    ct.resize(n);
12    init(_k1, _k2);
13    decompose(0,-1);
14 }
15 int dfs(int u, int p){
16     sz[u] = 1;
17     for (int v : t[u]){

5.2 Sum of distances

Given a tree, $f(u,v) :=$ distance from u to v in the tree, compute

$$\sum_{u,v} f(u,v)$$

. Time: $\mathcal{O}(n)$

```
1 vvi adj;
2 vi sum_going_down, sum_going_up, sz;
3
4 void dfs(int u, int p){
5     for (auto v : adj[u]){
6         if (v == p) continue;
7         dfs(v,u);
8         sz[u] += sz[v];
9         sum_going_down[u] += sum_going_down[v];
10    }
11    sum_going_down[u] += sz[u];
12 }
13
14 void dfs2(int u, int p, int par_ans){
15     int up_amount = sz[0] - sz[u];
16     sum_going_up[u] += par_ans + up_amount;
17     int sum = sum_going_down[u];
18     for (auto v : adj[u]){
19         if (v == p) continue;
20         int par_amount = sz[0] - sz[v];
21         dfs2(v,u, par_ans + par_amount + sum - (
22             sum_going_down[v]+sz[v]));
23     }
24 }
25 void solve(){
26     int n; cin >> n;
27     adj = vvi(n);
28     sum_going_down = sum_going_up = vi(n);
29     sz = vi(n,1);
30
31     for (int i = 1; i < n; i++){
32         int a, b; cin >> a >> b;
33         a--; b--;
34         adj[a].push_back(b);
35         adj[b].push_back(a);
36     }
37
38     dfs(0,0);
39     dfs2(0,0,0);
40
41     for (int i = 0; i < n; i++){
42         cout << sum_going_down[i]+sum_going_up[i] << ' ';
43     }
44     cout << endl;
45 }
```

5.3 Edge HLD

Sometimes the value is on the edges, for this few things need to change, but here is a template. Pre-computation:

$\mathcal{O}(n)$ Queries: $\mathcal{O}(\log^2 n)$

```

1 struct EdgeHLD {
2     int n, timer = 0;
3     vvii adj;
4     vi parent, depth, size, heavy, head, value;
5     vi tin, tout;
6
7     segtree seg;
8
9     void init(int _n, vvii& _adj) {
10         n = _n;
11         adj = _adj;
12         value.assign(n, 0);
13         parent.assign(n, -1);
14         depth.assign(n, 0);
15         size.assign(n, 0);
16         heavy.assign(n, -1);
17         head.assign(n, 0);
18         tin.assign(n, 0);
19         tout.assign(n, 0);
20         timer = 0;
21
22         // edgeWeight[v] = weight of edge (parent[v], v),
23         // for v>0
24         // root (0) has no parent, so its value is dummy
25         // (0)
26         dfs1(0,0,0);
27         dfs2(0, 0);
28
29         vi linear(n);
30         for (int u = 0; u < n; u++)
31             linear[tin[u]] = value[u]; // position stores
32             // edge weight
33
34         seg.init(linear);
35     }
36
37     int dfs1(int u, int p, int w) {
38         size[u] = 1;
39         parent[u] = p;
40         value[u] = w;
41         int max_sz = 0;
42         for (auto [v,w] : adj[u]) {
43             if (v == p) continue;
44             depth[v] = depth[u] + 1;
45             int sz = dfs1(v, u, w);
46             size[u] += sz;
47             if (sz > max_sz) {
48                 max_sz = sz;
49                 heavy[u] = v;
50             }
51         }
52         return size[u];
53     }
54
55     void dfs2(int u, int h) {
56         tin[u] = timer++;
57         head[u] = h;
58         if (heavy[u] != -1)
59             dfs2(heavy[u], h);
60         for (auto [v,w] : adj[u]) {
61             if (v != parent[u] && v != heavy[u])

```

```

61         dfs2(v, v);
62     }
63     tout[u] = timer;
64 }
65
66 // u deve ser o filho
67 void update_edge(int u, int val) {
68     seg.set(tin[u], val);
69 }
70
71 void rangeUpdate(int u, int v, int x) {
72     while (head[u] != head[v]) {
73         if (depth[head[u]] < depth[head[v]]) swap(u, v);
74         seg.rangeUpdate(tin[head[u]], tin[u] + 1, x);
75         u = parent[head[u]];
76     }
77     if (depth[u] > depth[v]) swap(u, v);
78     seg.rangeUpdate(tin[u] + 1, tin[v] + 1, x); // +1
79     // to skip LCA's edge
80 }
81
82 void update_subtree(int u, int x) {
83     // updates all edges in subtree of u (skip incoming
84     // edge to u)
85     seg.rangeUpdate(tin[u] + 1, tout[u], x);
86 }
87
88 segtree::node query(int u, int v) {
89     segtree::node res = seg.NEUTRAL;
90     while (head[u] != head[v]) {
91         if (depth[head[u]] < depth[head[v]]) swap(u, v);
92         res = seg.merge(res, seg.query(tin[head[u]], tin[
93             u] + 1));
94         u = parent[head[u]];
95     }
96     if (depth[u] > depth[v]) swap(u, v);
97     res = seg.merge(res, seg.query(tin[u] + 1, tin[v] +
98         1)); // skip LCA's edge
99     return res;
100 }
101
102 segtree::node query_subtree(int u) {
103     // query all edges in subtree of u
104     return seg.query(tin[u] + 1, tout[u]);
105 }
106 }

```

5.4 HLD - Heavy light decomposition

If you need to compute a function on a path in a tree and need to support value updates on nodes, HLD is the way. Pre-computation: $\mathcal{O}(n)$ Queries: $\mathcal{O}(\log^2 n)$

OBS: this implementation uses the same segtree as this notebook, with 0-indexing and open-closed interval convention. Ideally, just change the segtree to change the computed function, the HLD struct remains the same. OBS2: this template also supports mass updates (path/subtree) and subtree queries.

```

1 struct HLD {
2     int n, timer = 0;
3     vvi adj;
4     vi parent, depth, size, heavy, head, value;

```

```

5     vi tin, tout;
6
7     segtree seg;
8
9     void init(int _n, vi& _value, vvi& _adj) {
10         n = _n;
11         adj = _adj;
12         value = _value;
13         parent.assign(n, -1);
14         depth.assign(n, 0);
15         size.assign(n, 0);
16         heavy.assign(n, -1);
17         head.assign(n, 0);
18         tin.assign(n, 0);
19         tout.assign(n, 0);
20         timer = 0;
21
22         dfs1(0);
23         dfs2(0, 0);
24
25         vi linear(n);
26         for (int u = 0; u < n; u++)
27             linear[tin[u]] = value[u];
28
29         seg.init(linear);
30     }
31
32     int dfs1(int u) {
33         size[u] = 1;
34         int max_sz = 0;
35         for (int v : adj[u]) {
36             if (v == parent[u]) continue;
37             parent[v] = u;
38             depth[v] = depth[u] + 1;
39             int sz = dfs1(v);
40             size[u] += sz;

12             et_nodes.push_back(u);
13             et_deps.push_back(dep[u]);
14             tin[u] = timer++;
15             for (int v : adj[u]) if (v != p) {
16                 dep[v] = dep[u]+1;
17                 dfs(dfs, v, u);
18                 et_nodes.push_back(u);
19                 et_deps.push_back(dep[u]);
20             }
21             timer++;
22         };
23         dfs(dfs, 0, 0);
24
25         st.build(et_deps);
26     }
27
28     int get(int u, int v){
29         int tu = tin[u], tv = tin[v];
30         if (tu > tv) swap(tu, tv);
31         auto [val, id] = st.min(tu, tv);
32         return et_nodes[id];
33     }
34 };

```

5.6 LCA - binary lifting

Pre-computation: $\mathcal{O}(n \log n)$ Queries: $\mathcal{O}(\log n)$ OBS: just call `dfs(root)` before starting queries.

```

1 vvi adj, up;
2 vi tin, tout;
3 int timer = 0;
4
5 void dfs(int u, int p){
6     tin[u] = timer++;
7     for (auto v : adj[u]){
8         if (v == p) continue;
9         up[v][0] = u;
10        for (int dist = 1; dist < LOGN; dist++){
11            up[v][dist] = up[up[v][dist-1]][dist-1];
12        }
13        dfs(v);
14    }
15    tout[u] = timer++;
16 }
17
18 int isAncestor(int u, int v){
19     return tin[u] <= tin[v] && tout[v] <= tout[u];
20 }
21
22 int lca(int u, int v){
23     if (isAncestor(u,v)) return u;
24     if (isAncestor(v,u)) return v;
25     for (int dist = LOGN-1; dist >= 0; dist--){
26         if (!isAncestor(up[u][dist], v)) u = up[u][dist];
27     }
28     return up[u][0];
29 }

```

6 Problemas clássicos

6.1 2SAT

Struct for solving 2SAT problems that supports many types of boolean expressions. To add a negated literal use `u`

```

1 // para adicionar negacao usar ~u
2 // Ex: a clausula (a v !b) se traduz para add_or(a, ~b)
3 struct TwoSatSolver {
4     int n;
5     vvi adj, adjT;
6     vector<bool> vis, assignment;
7     vi topo, scc;
8
9     void build(int _n){
10         n = 2*_n;
11         adj.assign(n, vi());
12         adjT.assign(n, vi());
13     }
14
15     int get(int u){
16         if (u < 0) return 2*(~u)+1;
17         else return 2*u;
18     }
19
20     // u -> v
21     void add_impl(int u, int v){
22         u = get(u), v = get(v);
23         adj[u].push_back(v);

```

```

24         adjT[v].push_back(u);
25         adj[v^1].push_back(u^1);
26         adjT[u^1].push_back(v^1);
27     }
28
29     // u || v
30     void add_or(int u, int v){
31         add_impl(~u, v);
32     }
33
34     // u && v
35     void add_and(int u, int v){
36         add_or(u,u); add_or(v,v);
37     }
38
39     // u ^ v (equiv of x != v)
40     void add_xor(int u, int v){
41         add_impl(u, ~v);
42         add_impl(~u, v);
43     }
44
45     // u == v
46     void add_equals(int u, int v){

6.2 Next Greater Element

One of the classic stack applications. Easy to translate to

lower, leq or geq, just change the comparator of the while.

```

1 vi ngd(n, n);
2 stack<ii> st;
3 for (int i = 0; i < n; i++){
4     while (!st.empty() && st.top().first < h[i]){
5         ngd[st.top().second] = i;
6         st.pop();
7     }
8     st.emplace(h[i], i);
9 }

```

```

8 Math

8.1 Combinatorics (Pascal's Triangle)

Computes "n choose k". Requires factorials to be pre-computed. Time: $\mathcal{O}(\log ZAP)$

8.1.1 Combinatorial Analysis

Fundamental Counting Principles

- **Permutations:** The number of ways to arrange k items from a set of n distinct items.

$$P(n, k) = \frac{n!}{(n - k)!}$$

- **Combinations (Binomial Coefficient):** The number of ways to choose k items from a set of n distinct items, regardless of order.

$$\binom{n}{k} = C(n, k) = \frac{n!}{k!(n - k)!}$$

- **Combinations with Repetition (Stars and Bars):** The number of ways to choose k items of n types, allowing repetitions. Equivalently, the number of ways to distribute k identical balls into n distinct urns.

$$\binom{k + n - 1}{n - 1} = \binom{k + n - 1}{k}$$

Binomial Coefficient Properties and Pascal's Triangle

- **Pascal's Triangle**

$$[n = 0 : \binom{0}{0} \quad n = 1 : \binom{1}{0} \quad \binom{1}{1} \quad n = 2 : \binom{2}{0} \quad \binom{2}{1} \quad \binom{2}{2} \quad n = 3 : \binom{3}{0} \quad \binom{3}{1} \quad \binom{3}{2} \quad \binom{3}{3} \quad n = 4 : \binom{4}{0} \quad \binom{4}{1} \quad \binom{4}{2} \quad \binom{4}{3} \quad \binom{4}{4} \quad n = 5 : \binom{5}{0} \quad \binom{5}{1} \quad \binom{5}{2} \quad \binom{5}{3} \quad \binom{5}{4} \quad \binom{5}{5}]$$

- **Stifel's Relation:** Each element in Pascal's Triangle is the sum of the two elements immediately above it.

$$\binom{n}{k} = \binom{n - 1}{k} + \binom{n - 1}{k - 1}$$

- **Symmetry:** Elements of a row are symmetric with respect to the center. Choosing k elements is the same as choosing the $n - k$ elements to be left behind.

$$\binom{n}{k} = \binom{n}{n - k}$$

- **Row Sum:** The sum of all elements in row n of Pascal's Triangle (where the first row is $n = 0$) is equal to 2^n .

$$\sum_{k=0}^n \binom{n}{k} = 2^n$$

- **Hockey Stick Identity:** The sum of elements in a diagonal, starting at

$$\binom{r}{r}$$

and ending at

$$\binom{n}{r}$$

, is equal to the element in the next row and next column,

$$\binom{n + 1}{r + 1}$$

$$\sum_{i=r}^n \binom{i}{r} = \binom{n + 1}{r + 1}$$

- **Binomial Theorem:**

$$(x + y)^n = \sum_{k=0}^n \binom{n}{k} x^{n-k} y^k$$

- **Vandermonde's Identity:**

$$\sum_{j=0}^k \binom{n}{j} \binom{m}{k-j} = \binom{n+m}{k}$$

The easiest way to understand the identity is through a counting problem. Imagine you have a committee with m men and n women. How many ways can you form a subcommittee of k people?

Way 1 Direct Counting

You have a total of $m+n$ people and need to choose k of them. The number of ways to do this is simply:

$$\binom{m+n}{k}$$

Way 2 Counting by Cases

We can divide the problem into cases, based on how many men (j) are chosen for the subcommittee.

Case 0: Choose 0 men and k women. The number of ways is

$$\binom{m}{0} \binom{n}{k}$$

Case 1: Choose 1 man and $k-1$ women. The number of ways is

$$\binom{m}{1} \binom{n}{k-1}$$

Case 4: Choose j men and $k-j$ women. The number of ways is

$$\binom{m}{j} \binom{n}{k-j}$$

Other Important Concepts

- **Catalan Numbers:** A sequence of natural numbers that occurs in various counting problems (e.g., number of binary trees, balanced parenthesis expressions).

$$C_n = \binom{2n}{n} - \binom{2n}{n+1} = \frac{1}{n+1} \binom{2n}{n}$$

A commonly used combinatorial proof for the Catalan numbers involves counting the number of lattice (grid) paths from $(0,0)$ to (n,n) that do not cross above the diagonal $y = x$. Each such path consists of n rightward steps and n upward steps, and the Catalan number counts the number of these "Dyck paths" that never go above the diagonal.

- **Stirling Numbers of the Second Kind:** The number of ways to partition a set of n labeled objects into k non-empty unlabeled subsets. Denoted by $S(n, k)$ or

$$\{n \atop k\}$$

$$S(n, k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n$$

The Stirling numbers of the second kind can also be computed recursively:

$$S(n, k) = k \cdot S(n-1, k) + S(n-1, k-1)$$

with the boundary conditions:

$$S(0, 0) = 1; \quad S(n, 0) = 0 \text{ for } n > 0; \quad S(0, k) = 0 \text{ for } k > 0$$

- **Bell Number:** The Bell number B^n counts the total number of ways to partition a set of n labeled elements into any number (from 1 up to n) of non-empty, unlabeled subsets. It can also be written as a recurrence relation

$$B^n = \sum_{k=0}^n S(n, k)$$

- **Pigeonhole Principle:** If n items are put into m boxes, with $n > m$, then at least one box must contain more than one item.

```

1 // n escolhe k
2 // linha n, coluna k no triangulo (indexadas em 0)
3 int pascal(int n, int k){
4     int num = fat[n];
5     int den = (fat[k]*fat[n-k])%ZAP;
6     return (num*expbin(den, ZAP-2))%ZAP;
7 }

```

8.2 Convolutions

8.2.1 AND convolution

$$c[k] = \sum_{i \& j = k} a[i] \cdot b[j]$$

```

1 vector<mint<MOD>> and_conv(vector<mint<MOD>> a, vector<
    mint<MOD>> b){
2     int n = a.size(); // must be pow of 2
3     for (int j = 1; j < n; j <= 1) {
4         for (int i = 0; i < n; i++) {
5             if (i&j) {
6                 a[i^j] += a[i];
7                 b[i^j] += b[i];
8             }
9         }
10    }
11    for (int i = 0; i < n; i++) a[i] *= b[i];
12    for (int j = 1; j < n; j <= 1)
13        for (int i = 0; i < n; i++)
14            if (i&j) a[i^j] -= a[i];
15    return a;
16 }

```

8.2.2 GCD convolution

$$c[k] = \sum_{\gcd(i,j)=k} a[i] \cdot b[j]$$

```

1 vector<mint<MOD>> gcd_conv(vi a, vi b){
2     int n = (int)max(a.size(), b.size());
3     a.resize(n);
4     b.resize(n);
5     vector<mint<MOD>> c(n);
6     for (int i = 1; i < n; i++) {
7         mint<MOD> x = 0;
8         mint<MOD> y = 0;
9         for (int j = i; j < n; j += i) {
10             x += a[j];
11             y += b[j];
12         }
13         c[i] = x*y;
14     }
15     for (int i = n-1; i >= 1; i--)
16         for (int j = 2 * i; j < n; j += i)
17             c[i] -= c[j];
18     return c;
19 }

```

8.2.3 LCM convolution

$$c[k] = \sum_{\text{lcm}(i,j)=k} a[i] \cdot b[j]$$

```

1 vector<mint<MOD>> lcm_conv(vi a, vi b){
2     int n = (int)max(a.size(), b.size());
3     a.resize(n);
4     b.resize(n);
5     vector<mint<MOD>> c(n), x(n), y(n);
6     for (int i = 1; i < n; i++) {
7         for (int j = i; j < n; j += i) {
8             x[j] += a[i];
9             y[j] += b[i];
10        }
11        c[i] = x[i]*y[i];
12    }
13    for (int i = 1; i < n; i++)
14        for (int j = 2 * i; j < n; j += i)
15            c[j] -= c[i];
16    return c;
17 }

```

8.2.4 OR convolution

$$c[k] = \sum_{i|j=k} a[i] \cdot b[j]$$

```

1 vector<mint<MOD>> or_conv(vector<mint<MOD>> a, vector<
    mint<MOD>> b){
2     int n = a.size(); // must be pow of 2
3     for (int j = 1; j < n; j <= 1) {
4         for (int i = 0; i < n; i++) {
5             if (i&j) {
6                 a[i] += a[i^j];
7                 b[i] += b[i^j];
8             }
9         }
10    }
11    for (int i = 0; i < n; i++) a[i] *= b[i];
12    for (int j = 1; j < n; j <= 1)
13        for (int i = 0; i < n; i++)
14            if (i&j) a[i] -= a[i^j];
15    return a;
16 }

```

8.2.5 XOR convolution

$$c[k] = \sum_{i \oplus j = k} a[i] \cdot b[j]$$

```

1 void fwht(vector<mint<MOD>> &a, bool inv){
2     int n = a.size(); // must be pow of 2
3     for (int step = 1; step < n; step <= 1){
4         for (int i = 0; i < n; i += 2*step) {
5             for (int j = i; j < i+step; j++){
6                 auto u = a[j];
7                 auto v = a[j+step];
8                 a[j] = u+v;
9                 a[j+step] = u-v;

```

```

10     }
11     }
12 }
13 if (inv) for (auto &x : a) x /= n;
14 }
15
16 vector<mint<MOD>> xor_conv(vector<mint<MOD>> a, vector<
17     mint<MOD>> b){
18     int n = a.size();
19     fwht(a,0), fwht(b, 0);
20     for (int i = 0; i < n; i++) a[i] *= b[i];
21     fwht(a,1);
22     return a;
23 }

```

8.3 Extended Euclid

Time: $\mathcal{O}(\log n)$.

```

1 int extended_gcd(int a, int b, int &x, int &y) {
2     x = 1, y = 0;
3     int x1 = 0, y1 = 1;
4     while (b) {
5         int q = a / b;
6         tie(x, x1) = make_tuple(x1, x - q * x1);
7         tie(y, y1) = make_tuple(y1, y - q * y1);
8         tie(a, b) = make_tuple(b, a - q * b);
9     }
10    return a;
11 }

```

8.4 Factorization

Time: $\mathcal{O}(\sqrt{n})$

```

1 // O(sqrt(n)) fatores repetidos
2 vi fatora(int n) {
3     vi factors;
4     for (int x = 2; x*x <= n; x++) {
5         while (n % x == 0) {
6             factors.push_back(x);
7             n /= x;
8         }
9     }
10    if (n > 1) factors.push_back(n);
11    return factors;
12 }
13
14 // O(sqrt(n))
15 // Calcula a quantidade de divisores de um numero n.
16 int qtdDivisores(int n) {
17     int ans = 1;
18     for (int i = 2; i * i <= n; i += 2) {
19         int exp = 0;
20         while (n % i == 0) {
21             n /= i; exp++;
22         }
23         if (exp > 0) ans *= (exp + 1);
24         if (i == 2) i--;
25     }
26     if (n > 1) ans *= 2;
27     return ans;
28 }
29
30 // O(sqrt(n))

```

```

31 // Calcula a soma de todos os divisores de um numero n.
32 ll somaDivisores(int n) {
33     ll ans = 1;
34     for (int i = 2; i * i <= n; i += 2) {
35         if (n % i == 0) {
36             int exp = 0;
37             while (n % i == 0) {
38                 n /= i; exp++;
39             }
40             ll aux = expbin(i, exp + 1);
41             ans *= ((aux - 1) / (i - 1));
42         }
43         if (i == 2) i--;
44     }
45     if (n > 1) ans *= (n + 1);
46     return ans;
47 }
48
49 }

```

8.5 FFT - Fast Fourier Transform

Divide and conquer algorithm used for convolutions and polynomial multiplication. Vector size a is a power of 2. Time: $\mathcal{O}(n \log n)$ Space: $\mathcal{O}(n)$

```

1 void fft(vector<cd> &a, bool invert){
2     int len = a.size();
3     for(int i = 1, j = 0; i < len; i++){
4         int bit = len >> 1;
5         while(bit & j){
6             j ^= bit;
7             bit >>= 1;
8         }
9         j ^= bit;
10        if(i < j) swap(a[i], a[j]);
11    }
12    for(int l = 2; l <= len; l <= 1){
13        double ang = 2*PI/l * (invert ? -1: 1);
14        cd wd(cos(ang), sin(ang));
15        for(int i = 0; i < len; i += l){
16            cd w(1);
17            for(int j = 0; j < l/2; j++){
18                cd u = a[i+j], v = a[i+j+l/2];
19                a[i+j] = u+w*v;
20                a[i+j+l/2] = u-w*v;
21                w *= wd;
22            }
23        }
24    }
25    if(invert){
26        for(int i = 0; i < len; i++){
27            a[i] /= len;
28        }
29    }
30 }

```

8.6 Inclusion-Exclusion Principle

TODO: rewrite math statement

```

1 // Exemplo:
2 // Contar numeros de 1 a n divisveis por uma lista de
   primos.

```

```

3 int n;
4 vi primes;
5 int factors = primes.size();
6 int total_divisible = 0;
7
8 // Itera pelas bitmasks nao vazias de 'primes'
9 for (int i = 1; i < (1 << factors); i++) {
10    int current_lcm = 1;
11    int subset_size = 0;
12
13    // calcula lcm do subconjunto
14    for (int j = 0; j < factors; j++) {
15        if (i & (1<<j)) {
16            subset_size++;
17            current_lcm = lcm(current_lcm, primes[j]);
18            if (current_lcm > n) break;
19        }
20    }
21
22    if (current_lcm > n) {
23        continue;
24    }
25
26    int count = n / current_lcm;
27
28    // Aplica o Principio da Inclusao-Exclusao:
29    // Se o tamanho do subconjunto eh impar, adiciona.
30    // Se o tamanho do subconjunto eh par, subtrai.
31    if (subset_size & 1) {
32        total_divisible += count;
33    } else {
34        total_divisible -= count;
35    }
36 }

```

8.7 Legendre's formula

Computes the largest power of a prime p in $n!$

```

1 int legendre(int n, int p){
2     int ans = 0;
3     while(n>0){
4         n /= p; ans += n;
5     }
6     return ans;
7 }

```

8.8 Linear Sieve + Möbius Function

$$\mu(n) = \begin{cases} 1 & \text{if } n = 1 \\ (-1)^k & \text{if } n \text{ is a product of } k \text{ distinct primes} \\ 0 & \text{if } p^2 \mid n \text{ for some prime } p \end{cases}$$

8.8.1 Applications

- **Inclusion-Exclusion:** Naturally generates $1, -1, 0$ coefficients for prime factor sets.

- **Möbius Inversion:** Converts $g(n) = \sum_{d|n} f(d)$ to $f(n) = \sum_{d|n} \mu(d)g(\frac{n}{d})$. Often reduces $O(N)$ divisor sums to $O(\sqrt{N})$.
- **Dirichlet Convolution:** $\mu * 1 = \epsilon$. Core to sub-linear prefix sum algorithms (e.g., DuSieve) yielding $O(N^{2/3})$ time.

```

1 auto sieve = [](int n) -> pair<vi,vi> {
2     vi primes, mu(n+1);
3     mu[1] = 1;
4     vector<bool> is_prime(n+1, true);
5     is_prime[0] = is_prime[1] = false;
6     for (int i = 2; i <= n; ++i) {
7         if (is_prime[i]) {
8             primes.push_back(i);
9             mu[i] = -1;
10        }
11        for (int p : primes) {
12            if (i*p > n) break;
13            is_prime[i*p] = false;
14            if (i%p == 0) {
15                mu[i*p] = 0;
16                break;
17            }
18            mu[i*p] = -mu[i];
19        }
20    }
21    return {primes, mu};
22 };

```

8.9 Matrix template

A template for square matrices, used for solving linear recurrences with fast exponentiation, memory is on a 1D vector, but can be accessed with `A[i][j]` normally (custom `operator[]`)

```

1 template<typename T>
2 struct mat {
3     vector<T> m;
4     int n;
5
6     mat(int _n = 0, bool identity = false) : n(_n) {
7         m.resize(n*n);
8         if (!identity) return;
9         for (int i = 0; i < n; i++)
10             m[i*n+i] = 1;
11     }
12
13     mat& operator+=(const mat& o){
14         for (int i = 0; i < n; i++){
15             int ra = i*n;
16             for (int j = 0; j < n; j++){
17                 m[ra+j] += o.m[ra+j];
18             }
19         }
20         return *this;
21     }
22     mat& operator-=(const mat& o){
23         for (int i = 0; i < n; i++){
24             int ra = i*n;
25             for (int j = 0; j < n; j++){
26                 m[ra+j] -= o.m[ra+j];

```

```

27     }
28 }
29 return *this;
30 }
31 mat& operator+=(const mat& o){
32     vector<T> ans(n*n);
33     for (int i = 0; i < n; i++){
34         for (int k = 0; k < n; k++){
35             int ra = i*n, rb = k*n;
36             for (int j = 0; j < n; j++){
37                 ans[ra+j] += m[ra+k] * o.m[rb+j];
38             }
39         }
40     }
41     this->m = ans;
42     return *this;

45 };

```

8.11 Modular Inverse

If m is prime, can use binary exponentiation to compute a^{p-2} (Fermat's Little Theorem).

This code works for non-prime m , as long as it is coprime to a .

Time: $\mathcal{O}(\log m)$

```

1 int modInverse(int a, int m) {
2     int x, y;
3     int g = extendedGcd(a, m, x, y);
4     if (g != 1) return -1;
5     return (x % m + m) % m;
6 }

```

8.12 Number Theoretic Transform (NTT)

NTT is a fast algorithm (analogous to FFT) for polynomial multiplication modulo a special prime. It requires a prime modulus $p = c \cdot 2^k + 1$ (a "primitive root prime") and a primitive 2^k -th root of unity modulo p .

- **Prime Choices:** To use NTT, pick a modulus and a matching primitive root (see table below). For arbitrary moduli (e.g., $10^9 + 7$), multiply with several NTT-friendly primes and reconstruct with CRT (see `crt_multiply`).

- **Time Complexity:** $\mathcal{O}(n \log n)$ for polynomial multiplication.

8.12.1 NTT-Friendly Primes and Roots

NTT-friendly primes and their primitive roots:

- Mod: 998244353, Root: 3, Max N: 2^{23}
- Mod: 734003201, Root: 3, Max N: 2^{20}
- Mod: 167772161, Root: 3, Max N: 2^{25}
- Mod: 469762049, Root: 3, Max N: 2^{26}

Use the modulus as MOD and the root as ROOT when instantiating the NTT.

- For large/concrete moduli, see `crt_multiply` in the code for a multi-modulus solution with Chinese Remainder Theorem (CRT).

```
1 namespace NTT{
2   template<typename T, ll MOD, ll ROOT>
3   void transform(vector<T>& a, bool invert) {
4     int n = a.size();
5
6     for (int i = 1, j = 0; i < n; i++) {
7       int bit = n >> 1;
8       for (; j & bit; bit >>= 1) j ^= bit;
9       j ^= bit;
10      if (i < j) swap(a[i], a[j]);
11    }
12
13    for (int len = 2; len <= n; len <= 1) {
14      T wlen = T::power(ROOT, (MOD - 1) / len);
15      if (invert) wlen = T::inv(wlen);
16      for (int i = 0; i < n; i += len) {
17        T w = 1;
18        for (int j = 0; j < len / 2; j++) {
19          T u = a[i + j], v = a[i + j + len / 2] * w;
20          a[i + j] = u + v;
21          a[i + j + len / 2] = u - v;
22          w *= wlen;
23        }
24      }
25    }
26
27    if (invert) {

```

9.2 Basic elements - geometry lib

- Basic elements for using the geometry lib, contains points, vector operations and distances between points, distance between point and segment, distance between segments, segment intersection check, orientation check (ccw).
- Always use long double for floating point. Only use floating point if indispensable.
- For $a == b$, use $|a - b| < \text{eps}$!!!!

Time: $\mathcal{O}(1)$

9.2.1 Polygon Area

- Heron's Formula for triangle area:

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$

, where a , b , and c are the triangle sides and $s = (a + b + c)/2$

TODO Shoelace

- Pick's Theorem for polygon area with integer coordinates:

$$A = a + b/2 - 1$$

, where a is the number of integer coordinates inside the polygon and b is the number of integer coordinates on the polygon boundary. b can be calculated

for each edge as

$$b = \gcd(x_i + 1 - x_i, y_i + 1 - y_i) + 1$$

Polygon Area Time: $\mathcal{O}(n)$

9.2.2 Point in polygon

Sum of edge angles relative to the point must sum to 2π
Time: $\mathcal{O}(n \log n)$

```
